## ABSTRACT

As the terms are used here, a *body* in  $\mathbb{R}^d$  is a compact convex set with nonempty interior, and a *polytope* is a body that has only finitely many extreme points. The class of all bodies whose interior includes the origin 0 is denoted by  $C_0^d$ . A set  $X$  is *symmetric* if  $X = -X$ . The *ray-oracle* of a body  $C \in C_0^d$  is the function  $O_C$  which, accepting as input an arbitrary ray  $R$  issuing from 0, produces the point at which  $R$  intersects  $C$ 's boundary. This paper is concerned with a few central aspects of the following general question: Given certain information about  $C$ , what additional information can be obtained by questioning the ray-oracle, and how efficiently can it be obtained? It is assumed that the usual arithmetic operations in  $\mathbb{R}^d$  are available at no cost, so the efficiency of an algorithm is measured solely in terms of its number of calls to the ray-oracle.

The paper discusses two main problems, the first of which – the *containment problem* – arose from a question in abstract numerical analysis. Here the goal is to *construct* a polytope  $P$  (not necessarily in any sense a small one) that contains  $C$ , where this requires precise specification of  $P$ 's vertices. There are some sharp positive results for the case in which  $d = 2$  and  $C$  is known not to be too asymmetric, but the main result on the containment problem is negative. It asserts that when  $d \geq 3$  and the body is known only to be rotund and symmetric, there is no algorithm for the containment problem. This is the case even when there is available a certain master oracle whose question-answering power is much greater than that of  $C$ 's ray-oracle. However, it turns out that even when there is no additional information about  $C$ , the following relaxation of the containment problem admits

an algorithmic solution based solely on the ray-oracle: Construct a polytope containing  $C$  or conclude that  $C$ 's centered condition number exceeds a certain bound.

In the other main problem -- the *reconstruction problem* -- it is known only that  $C$  is itself a polytope and the problem is to construct  $C$  with the aid of a finite number of calls to the ray-oracle. That is accomplished with a number of calls that depends on the combinatorial complexity of  $C$ .

ABSTRACT

As the terms are used here, a body in  $\mathbb{R}^d$  is a compact convex set with nonempty interior, and a polytope is a body that has only finitely many extreme points. The class of all bodies whose interior includes the origin  $\theta$  is denoted by  $\mathcal{C}_\theta^d$ . A set  $X$  is symmetric if  $X = -X$ . The ray-oracle of a body  $C \in \mathcal{C}_\theta^d$  is the function  $\mathcal{R}_C$  which, accepting as input an arbitrary ray  $R$  issuing from  $\theta$ , produces the point at which  $R$  intersects  $C$ 's boundary. This paper is concerned with a few central aspects of the following general question: Given certain information about  $C$ , what additional information can be obtained by questioning the ray-oracle, and how efficiently can it be obtained? It is assumed that the usual arithmetic operations in  $\mathbb{R}^d$  are available at no cost, so the efficiency of an algorithm is measured solely in terms of its number of calls to the ray-oracle.

The paper discusses two main problems, the first of which -- the containment problem -- arose from a question in abstract numerical analysis. Here the goal is to construct a polytope  $P$  (not necessarily in any sense a small one) that contains  $C$ , where this requires precise specification of  $P$ 's vertices. There are some sharp positive results for the case in which  $d = 2$  and  $C$  is known not to be too asymmetric, but the main result on the containment problem is negative. It asserts that when  $d \leq 3$  and the body is known only to be round and symmetric, there is no algorithm for the containment problem. This is the case even when there is available a certain master oracle whose question-answering power is much greater than that of  $C$ 's ray-oracle. However, it turns out that even when there is no additional information about  $C$ , the following relaxation of the containment problem admits
